

## Very low drop voltage regulator

#### **Features**

- Operating DC supply voltage range 6 V to 28 V
- Transient supply voltage up to 40 V
- Extremely low quiescent current
- High precision output voltage
- Output current capability up to 500 mA
- Very low dropout voltage less than 0.6 V
- Reset circuit sensing the output voltage
- Programmable reset pulse delay with external capacitor
- Thermal shutdown and short circuit protections

### **Description**

The L4925 is a monolithic integrated 5 V voltage regulator with a very low dropout output and additional functions such as power-on reset and programmable reset delay time.

It is designed for supplying microcomputer controlled systems especially in automotive applications.

V <sub>RL</sub>	Reset output low voltage	$R_{RES} = 10 \text{ K}\Omega \text{ to } V_O; V_S = \ge 3 \text{ V}$			0.4	V
I <sub>RH</sub>	Reset output high leakage current	V <sub>RES</sub> = 5 V			1	μΑ
V <sub>CTth</sub>	Delay comparator threshold			2		V
V <sub>CTth hy</sub>	Delay comparator threshold hysteresis			200		mV

### 3 Functional description

The L4925 is a monolithic integrated voltage regulator, based on the STM modular voltage regulator approach. Several outstanding features and auxiliary functions are implemented to meet the requirements of supplying microprocessor systems in automotive applications. Nevertheless, it is suitable also in other applications where the present functions are required. The modular approach of this device allows to get easily also other features and functions when required.

#### 3.1 Voltage regulator

The voltage regulator uses an Isolated Collector Vertical PNP transistor as a regulating element. With this structure very low dropout voltage at currents up to 500 mA is obtained.

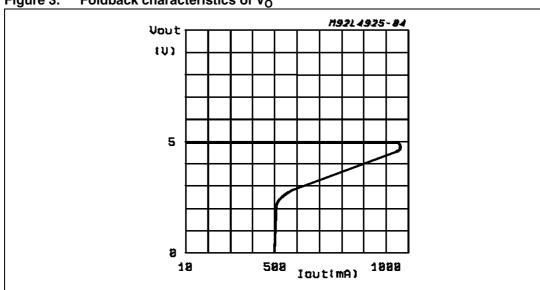

Figure 3. Foldback characteristics of V<sub>O</sub>

The dropout operation of the standby regulator is maintained down to 3 V input supply voltage. The output voltage is regulated up to the transient input supply voltage of 35 V. With this feature no functional interruption due to overvoltage pulses is generated.

The typical curve showing the standby output voltage as a function of the input supply voltage is shown in *Figure 4*.

The current consumption of the device (quiescent current) is less than 250  $\mu$ A. To reduce the quiescent current peak in the undervoltage region and to improve the transient response in this region, the dropout voltage is controlled.

The quiescent current as a function of the supply input voltage is shown in *Figure 5*.

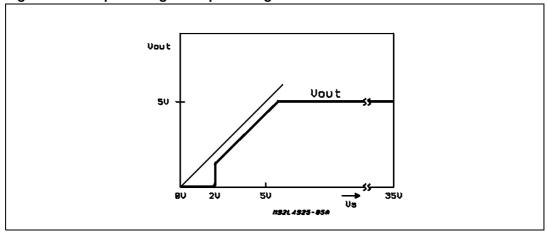

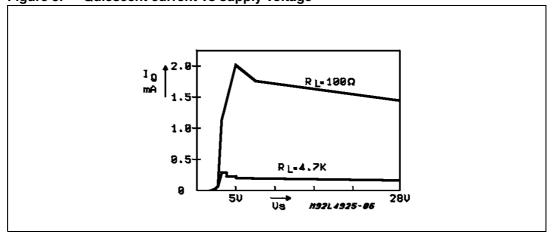

Figure 4. Output voltage vs input voltage

#### 3.2 Reset circuit

The block circuit diagram of the reset circuit is shown in *Figure 6*. The reset circuit supervises the output voltage. The reset threshold of 4.5 V is defined with the internal reference voltage and standby output divider. The reset pulse delay time  $t_{RD}$ , is defined with the charge time of an external capacitor CT:

$$t_{RD} = \frac{C_T \cdot 2V}{2\mu A}$$

The reaction time of the reset circuit originates from the discharge time limitation of the reset capacitor CT and it is proportional to the value of CT. The reaction time of the reset circuit increases the noise immunity. Standby output voltage drops below the reset threshold only a bit longer than the reaction time results in a shorter reset delay time.

The nominal reset delay time is generated for standby output voltage drops longer than approximately 50 ms. The typical reset output waveforms are shown in *Figure 7*.

Figure 6. Block circuit diagram

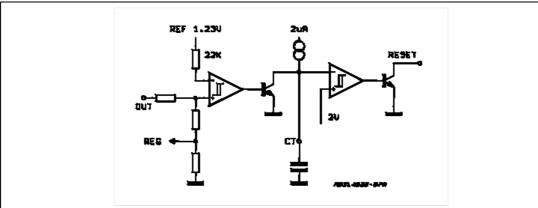

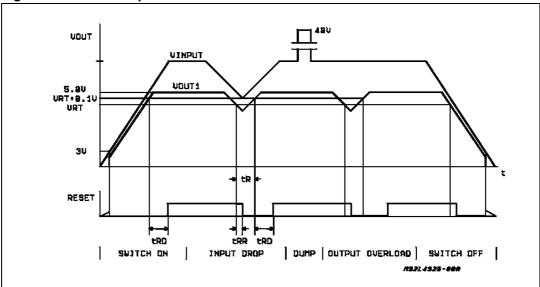

Figure 7. Reset output waveforms

# 4 Application information

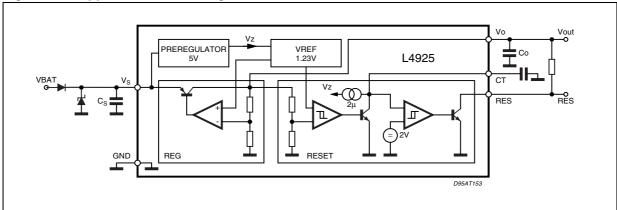

### 4.1 Supply voltage transients

High supply voltage transients can cause a reset output signal disturbance.

For supply voltage greater than 8 V the circuit shows a high immunity of the reset output against supply transients of more than 100 V/ms. For supply voltage lower than 8 V, supply transients of more than 0.4 V/ms. can cause a reset signal disturbance.

### 4.2 Application circuit

Figure 8. Application circuit diagram

For stability:  $C_S \ge$  1  $\mu F;~C_O \ge$  10  $\mu F;~ESR \le$  2.5  $\Omega$  at 10 KHz

Recommended for application:  $C_S = C_O = 10 \mu F$  to 100  $\mu F$
