

Current Mode PWM Controller withIntegrated Start-up Circuit and Op Amp

POWER MANAGEMENT

Description

The SC4812 is a highly integrated current mode PWM controller designed for isolated or non-isolated dc-dc converters in telecommunication and data communication applications. It minimizes the amount of external discrete components needed and leads to substantial cost and space saving converter designs.

The circuitry of the SC4812 includes an integrated high voltage start-up circuit suitable for telecom/industrial voltage applications. It is disabled during regular operation and improves efficiency. Current mode control with leading-edge blanking simplifies control loop design and internal ramp compensation circuit stabilizes the current loop when operating above 50% duty cycle. Internal error amplifier could be used for non-isolated applications.

Features

- Wide input range 12V to 90V
- ◆ High-voltage start-up circuit
- Current mode control
- ◆ Transconductance error amplifier
- Leading-edge blanking
- ◆ Cycle by cycle current limit
- ◆ Programmable external soft-start
- Thermal shutdown
- ◆ SO-8 package. Fully WEEE and RoHS compliant

Applications

- ◆ IP phones, PoE
- Telecom isolated converters
- ◆ Off-line isolated power supplies
- Instrumentation power supplies
- Battery chargers

Typical Application Circuit

Pin Configuration

Ordering Information

Part Number	Top Mark	Package
SC4812STRT ⁽¹⁾⁽²⁾	SC4812	SO-8
SC4812EVB	Evaluatio	n Board

Notes:

- (1) Only available in tape and reel packaging. A reel contains 2500 devices.
- (2) Lead free product. This product is fully WEEE and RoHS compliant.

Absolute Maximum Ratings

Exceeding the specifications below may result in permanent damage to the device, or device malfunction. Operation outside of the parameters specified in the Electrical Characteristics section is not implied. Exposure to Absolute Maximum rated conditions for extended periods of time may affect device reliability.

Parameter	Symbol	Maximum	Units
Input Voltage	V _{IN}	-0.5 to 100	V
Supply Voltage	V _{cc}	-0.5 to 18	V
Supply Current	I _{cc}	20	mA
FB, COMP, CS, and SS/SHDN to GND		-0.5 to 7	V
OUT Peak Current		±1	А
Continuous Power Dissipation	P _D	Internally limited	W
Junction Temperature Range	T _J	-40 to +150	°C
Thermal Resistance (1)	θ _{JA}	105	°C/W
Storage Temperature Range	T _{STG}	-65 to +150	°C
Lead Temperature (Soldering) 10 Sec.	T _{LEAD}	+300	°C

Note:

(1) Mounted to 3" x 4.5", 4 layer FR4 PCB in still air per JESD51 standards.

Electrical Characteristics

Unless specified: V_{CC} = 12V, a 10uF capacitor connects V_{CC} to GND, V_{CS} = 0, V_{IN} = 48V, a 0.1uF capacitor connects SS/SHDN to GND, OUT = open circuit, FB = GND, T_A = T_J = -40 to +125°C. Typical values are at T_A = 25°C

Parameter	Test Conditions	Min	Тур	Max	Unit
Startup/Winding Regulator					
V _N Input Voltage Range		12		90	V

Fall Time	C _L = 1nF		35		nS	
Thermal Shutdown					•	
Thermal Shutdown Temperature			150		°C	
Thermal Hysteresis			25		°C	

Note:

(1) This device is ESD sensitive. Use of standard ESD handling precautions is required.

Pin Descriptions

Pin #	Pin Name	Pin Function
1	VIN	High voltage startup input. Connect directly to an input voltage between 12 to 90V. Connects internally to a high voltage linear regulator that generates $V_{\rm cc}$ during startup.
2	FB	Feedback input to the internal transconductance error amplifier. V _{FB} sensed the regulated output voltage through an external resistor divider.
3	COMP	Internal transconductance error amplifier output. Compensation network of the overall loop is placed between this pin and GND.
4	SS/SHDN	Soft start timing capacitor connection. Ramp time to full current limit is approximately TBD ms/nF. This pin is also the reference voltage output. Bypass with a minimum 10nF capacitor to GND. The device goes into shutdown when V _{SS_SHDN} is pulled below 0.25V.
5	CS	Current sense input. Turns power switch off if $V_{\rm cs}$ rises above 465mV for cycle-by-cycle current limiting. CS is also the feedback for the current mode controller. CS is connected to the PWM comparator through a leading edge blanking circuit.
6	GND	Ground.
7	OUT	Gate drive. Drives a high voltage external N-channel power MOSFET.
8	VCC	Supply voltage. Provides power for entire IC. $V_{\rm CC}$ is regulated from $V_{\rm N}$ during startup. Bypass $V_{\rm CC}$ with a 10uF tantalum capacitor in parallel with 0.1uF ceramic capacitor to GND.

Block Diagram

Application Information

Introduction

The SC4812 is a 8 pin peak current mode controlled PWM controller for isolated or non-isolated DC-DC switching power supplies. It features an internal startup regulator, programmable external soft start and programmable cycle -by-cycle current limit. It operates in a fixed frequency at 260KHz.

The SC4812 can be applied in a flyback or forward topology with the input voltage ranging from 36V to 75V.

Startup Regulator

The internal startup regulator of the SC4812 makes its initial startup without a lossy startup resistor or external startup circuitry to save cost and board space. As input voltage exceeds 12V, it provides regulated 7.4V to $V_{\rm cc}$ which is with the maximum turn-on voltage 6.7V.

Soft-Start/Shutdown and V_{cc} Lockout

During power startup, the output voltage has to ramp up in a controlled manner to avoid overshoot. The SC4812 internal non-inverting terminal to the error amplifier is connected to the soft-start pin, which forces the internal 2.5V reference to gradually ramp up during power startup. In a non-isolated application, as the internal error amplifier is used, output voltage of a converter ramps up with close loop startup fashion smoothly. In case of an isolated application in which the internal error amplifier may not be used, isolated voltage feedback is through an opto-coupler and connected to the COMP pin. During power startup, the COMP pin will follow the soft-start pin voltage through an internal diode.

Soft-start operation begins when SS/SHDN ramps above 0.7V. When soft-start completed, SS/SHDN is regulated to 2.50V, the internal voltage reference. Pull SS/SHDN below 0.5V to disable the controller.

Undervoltage lockout shuts down the controller when $V_{\rm cc}$ is less than 5.5V. The internal startup regulator and the reference remain on during shutdown.

Current-Sense

The function of the CS pin is to limit the peak current through the MOSFET. Current is sensed at CS as a voltage across a sense resistor between the source of the MOSFET and GND. An RC filter is recommended to connect CS to the sense resistor to reduce effect of the MOSFET turn-on leading edge spike and noise. Select the current-sense resistor with the following equation:

$$R_{S} = 0.465V/(1.2xI_{LIM\ PRI})$$

where $I_{\text{LIM_PRI}}$ is the maximum peak primary-side current. When VCS > 465mV, the power MOSFET turns off after 70nS propagation delay from the switch current reaches the trip point to the driver.

PWM Comparator and Slope Compensation

The SC4812 runs fixed 260 KHz frequency by an internal oscillator. At the beginning of each switching cycle, the OUT pin switches the MOSFET on. the OUT pin switches off after the 80% maximum duty cycle has been reached, regardless of the feedback.

Since an artificial slope is required for current-mode operation when duty cycle is larger than 50%, the SC4812 uses an internal ramp generator for slope compensation. The internal ramp signal is reset at the beginning of each cycle and slews at $26\text{mV/}\mu\text{S}$.

The PWM comparator compares the instantaneous primary peak current to the feedback error signal through the opto-coupler, the internal offset and slope compensation and determine when to turn off the MOSFET. In steady state operation, the MOSFET turns off when:

$$I_{LIM_PRI} \cdot R_S > V_{OPTO} - V_{OFFSET} - V_{SLOPE}$$

where I_LIM_PRI is the current on the primary side through the MOSFET. V_{OFFSET} is 1.5V internal offset voltage and V_{SLOPE} is the artificial ramp starting at with slew rate 26mV/ μS .

When selecting an inductor in a forward-converter or magnetizing inductance in a flyback-converter, the following condition must be met to avoid control-loop subharmonic oscillations:

$$\frac{N_S}{N_P} \times \frac{K \times R_S \times V_O}{L} = 26 \text{mV} / \mu S$$

where K = 0.5 TO 1, AND N_s and N_p are the turns of the main transformer on secondary and primary side respectively. L is the output inductor on secondary side in a forward-converter or magnetizing inductance on secondary side in a flyback-converter.

Applications Information (Cont.)

PCB Layout Guideline

PCB layout is very critical, and the following should be considered to insure proper operation of the SC4812. High switching currents are present in applications and their effect on ground plane must be understood and minimized.

- 1) The high power parts of the circuit should be placed on a board first. A ground plane should be used. Isolated or semi-isolated areas of the ground plane may be deliberately introduced to constrain ground currents to particular areas, for example the input capacitor and the main switch FET ground.
- 2) The loop formed by the Input Capacitor(s) (Cin), the main transformer and the main switch FET must be kept as small as possible. This loop contains all the high fast transient switching current. Connections should be as wide and as short as possible to minimize loop inductance. Minimizing this loop area will a) reduce EMI, b) lower ground injection currents, resulting in electrically "cleaner" grounds for the rest of the system and c) minimize source ringing, resulting in more reliable gate switching signals.
- 3) The connection between FETs and the main transformer should be a wide trace or copper region. It should be as short as practical. Since this connection has fast voltage transitions, keeping this connection short will minimize EMI.
- 4) The output capacitor(s) (Cout) should be located as close to the load as possible. Fast transient load currents are supplied by Cout only. Connections between Cout and the load must be short, wide copper areas to minimize inductance and resistance.
- 5) A 0.1uF to 1uF ceramic capacitor should be directly connected between VCC and GND and a 1uF to 4.7uF. The SC4812 is best placed over a quiet ground plane area. Avoid pulse currents in the Cin and the main switch FET loop flowing in this area. GND should be returned to the ground plane close to the package and close to the ground side of (one of) the VCC supply capacitor(s). Under no circumstances should GND be returned to a ground inside the Cin and the main switch FET loop. This can be achieved by making a star connection between the quiet GND planes that the SC4812 will be connected to and the noisy high current GND planes connected to the FETs.

- 6) The feed back connection between the error amplifier and the FB pin should be kept as short as possible, and the GND connections should be to the quiet GND used for the SC4812.
- 7) If an opto-coupler is used for isolation, quiet primary and secondary ground planes should be used. The same precautions should be followed for the primary GND plane as mentioned in item 5. For the secondary GND plane, the GND plane method mentioned in item 4 should be followed.
- 8) All the noise sensitive components such as VCC bypass capacitor, COMP resistor/capacitor network, current sensing circuitry and feedback circuitry should be connected as close as possible to the SC4812. The GND return should be connected to the quiet SC4812 GND plane.
- 9) The connection from the OUT of the SC4812 should be minimized to avoid any stray inductance. If the layout can not be optimized due to constraints, a small Schottky diode may be connected from the OUT pin to the ground directly at the IC. This will clamp excessive negative voltages at the IC.

Outline Drawing - SO-8

NOTES:

- 1. CONTROLLING DIMENSIONS ARE IN MILLIMETERS (ANGLES IN DEGREES).
- 2. DATUMS -A- AND -B- TO BE DETERMINED AT DATUM PLANE -H-
- DIMENSIONS "E1" AND "D" DO NOT INCLUDE MOLD FLASH, PROTRUSIONS OR GATE BURRS.
- 4. REFERENCE JEDEC STD MS-012, VARIATION AA.

Land Pattern - SO-8
