**FUNCTIONAL BLOCK DIAGRAM**

**GENERAL DESCRIPTION**

The ADG221 and ADG222 are monolithic CMOS devices comprising four independently selectable switches. On-chip latches facilitate microprocessor interfacing. They are designed on an enhanced LC<sup>2</sup>MOS process which gives an increased signal handling capability of ±15V. These switches also feature high switching speeds and low  $R_{ON}$ .

The ADG221 and ADG222 consist of four SPST switches. They differ only in that the digital control logic is inverted. All devices exhibit break before make switching action. Inherent in the design is low charge injection for minimum transients when switching the digital inputs.

**PRODUCT HIGHLIGHTS**

1. **Easily Interfaced:**  
Digital inputs are latched with a  $\overline{WR}$  signal for microprocessor interfacing. A 5V regulated supply is internally generated permitting wider tolerances on the supplies without affecting the TTL digital input switching levels.
2. **Single Supply Operation:**  
For applications where the analog signal is unipolar (0V to 15V), the switches can be operated from a single +15V supply.
3. **Low Leakage:**  
Leakage currents in the range of 500pA make these switches suitable for high precision circuits. The added feature of Break-before-Make switching allows for multiple outputs to be tied together for multiplexer applications while keeping leakage errors to a minimum.

**TIMING AND CONTROL SEQUENCE**

Figure 2 shows the timing sequence for latching the switch digital inputs (IN1 – IN4). The latches are level sensitive and, therefore, while  $\overline{WR}$  is held low the latches are transparent and the switches respond to the digital inputs. The digital inputs are latched on the rising edge of  $\overline{WR}$ .
